# ***EXPERIMENT NO.1***

## **Aim**

Draw a line using DDA algorithm.

## **Theory**

A linear DDA starts by calculating the smaller of  $dy$  or  $dx$  for a unit increment of the other. A line is then sampled at unit intervals in one coordinate and corresponding integer values nearest the line path are determined for the other coordinate.

Considering a line with positive slope, if the slope is less than or equal to 1, we sample at unit  $x$  intervals ( $dx=1$ ) and compute successive  $y$  values as

Subscript  $k$  takes integer values starting from 0, for the 1st point and increases by 1 until endpoint is reached.  $y$  value is rounded off to nearest integer to correspond to a screen pixel.

For lines with slope greater than 1, we reverse the role of  $x$  and  $y$  i.e. we sample at  $dy=1$  and calculate consecutive  $x$  values as

Similar calculations are carried out to determine pixel positions along a line with negative slope. Thus, if the absolute value of the slope is less than 1, we set  $dx=1$  if i.e. the starting extreme point is at the left.

## **Program**

```
#include<bits/stdc++.h>
#include<graphics.h>
#define ll long long int
using namespace std;
int main()
{
    int gd = DETECT, gm, tmp = 0;

    ll x1 = 0, x2 = 0, y1 = 0, y2 = 0, dx = 0, dy = 0;
    ll steps = 0, xinc = 0, yinc = 0, x = 0, y = 0;

    cin >> x1 >> y1;
```

```

cin >> x2 >> y2;

dx = x2 - x1;
dy = y2 - y1;

if(abs(dx) > abs(dy)) steps = abs(dx);
else steps = abs(dy);

xinc = dx / steps;
yinc = dy / steps;

x += xinc;
y += yinc;

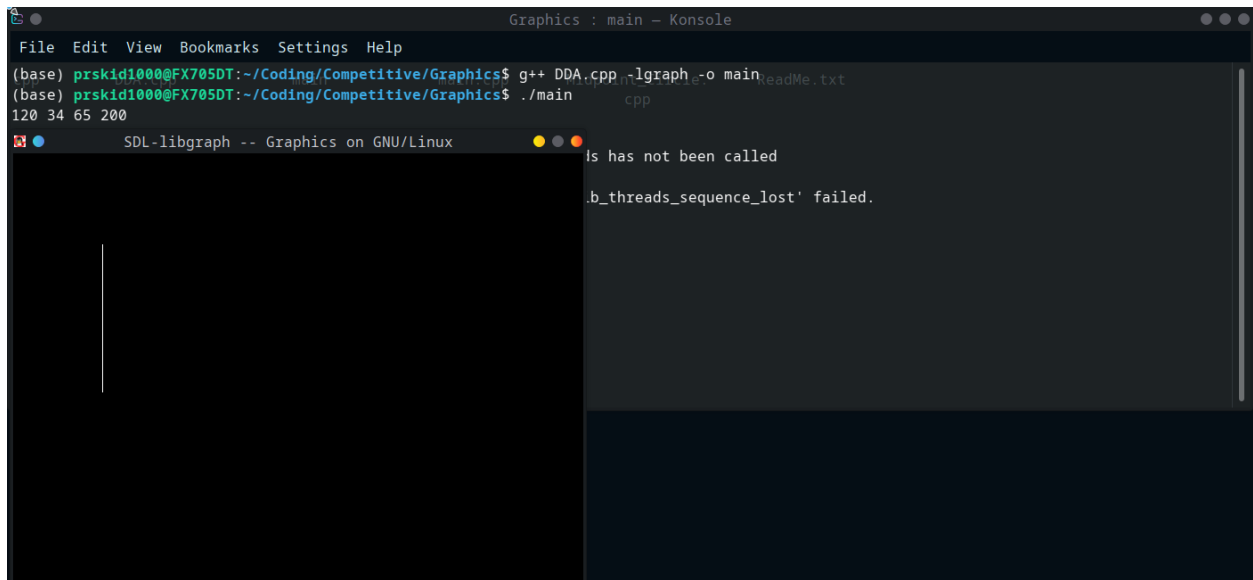

//declare all variables before it
initgraph(&gd,&gm, NULL);
//draw here

for(II i = 0; i < steps; i++)
{
    x += xinc;
    y += yinc;
    putpixel(100 + x, 100 + y, 15);
    delay(300);
}

//draw ends
getche();
closegraph();
return 0;
}

```

# ***EXPERIMENT NO.2***

## **Aim**

Draw a line using Bresenham's algorithm

## **Theory**

Let's define  $f(x,y) = 0 = ax + by + c$

$$D = f(x_0 + 1, y_0 + 0.5) - f(x_0, y_0)$$

If  $D > 0$  choose  $(x_0 + 1, y_0)$  and  $\text{del}(D) = \text{del}(y)$

If  $D > 0$  choose  $(x_0 + 1, y_0 + 1)$  and  $\text{del}(D) = \text{del}(y) - \text{del}(x)$

One performance issue is the  $\frac{1}{2}$  factor in the initial value of D. Since all of this is about the sign of the accumulated difference, then everything can be multiplied by 2 with no consequence

## **Program**

```
#include<bits/stdc++.h>
#include<graphics.h>
#define ll long long int
using namespace std;

int main()
{
    int gd = DETECT, gm, tmp = 0;

    ll x1 = 0, x2 = 0, y1 = 0, y2 = 0, dx = 0, dy = 0, p;

    cin >> x1 >> y1;
    cin >> x2 >> y2;
```

```
dx = x2 - x1;  
dy = y2 - y1;
```

```
//declare all variables before it  
initgraph(&gd,&gm, NULL);  
//draw here
```

```
if(dy > dx)  
{  
    p = 2*(dy - dx);  
    for(; x1 <= x2; x1++)  
    {  
        if(p < 0)  
        {  
            p = p + 2 * dy;  
        }  
        else  
        {  
            y1++;  
            p = p + 2 * dy - dx;  
        }  
        putpixel(100 + x1, 100 + y1, 15);  
        delay(300);  
    }  
}  
else  
{  
    p = 2*(dx - dy);  
    for(; y1 <= y2; y1++)  
    {  
        if(p < 0)  
        {  
            p = p + 2 * dx;  
        }  
        else  
        {  
            x1++;  
            p = p + 2 * dx - dy;  
        }  
        putpixel(100 + x1, 100 + y1, 15);
```

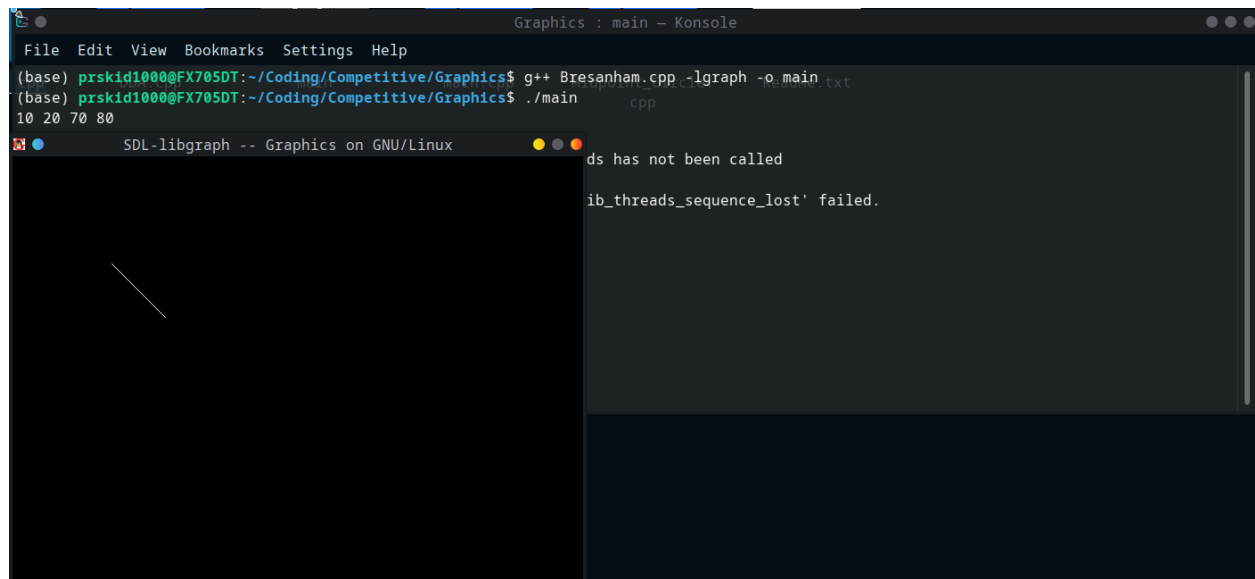

```

        delay(300);
    }
}

//draw ends
getche();
closegraph();
return 0;
}

```

## Output

# EXPERIMENT NO.3

## Aim

Draw a circle using midpoint algorithm.

## Theory

The function of a circle i.e.:  $f_{circle}(x,y) = x^2 + y^2 - r^2$

- If  $f_{circle} < 0$  then  $x, y$  is inside the circle boundary.
- If  $f_{circle} > 0$  then  $x, y$  is outside the circle boundary.
- If  $f_{circle} = 0$  then  $x, y$  is on the circle boundary.

$p_k = f_{circle}(x_{k+1}, y_{k-1/2})$  where  $p_k$  is a decision parameter and in this  $\frac{1}{2}$  is taken because it is a midpoint value through which it is easy to calculate value of  $y_k$  and  $y_{k-1}$ . i.e.  $p_k = (x_{k+1})^2 + (y_{k-1/2})^2 - r^2$

If  $p_k < 0$  then midpoint is inside the circle in this condition we select  $y$  is  $y_k$  otherwise we will select next  $y$  as  $y_{k-1}$  for the condition of  $p_k > 0$ .

If  $p_k < 0$  then  $y_{k+1} = y_k$ , by this the plotting points will be  $(x_{k+1}, y_k)$ . By this the value for the next point will be given as:  $P_{k+1} = p_k + 2(x_{k+1}) + 1$

If  $p_k > 0$  then  $y_{k+1} = y_{k-1}$ , by this the plotting points will be  $(x_{k+1}, y_{k-1})$ . By this the value of the next point will be given as:  $P_{k+1} = p_k + 2(x_{k+1}) + 1 - 2(y_{k+1})$   
 $P_0 = f_{circle}(1, r-1/2)$

This is taken because of  $(x_0, y_0) = (0, r)$   
i.e.  $p_0 = 5/4 - r$  or  $1 - r$ , ( $1 - r$  will be taken if  $r$  is integer)

## Program

```
#include<bits/stdc++.h>
#include<graphics.h>
#define ll long long int
#define ld long double
using namespace std;

int main()
{
    int gd = DETECT, gm, tmp = 0;

    ld r = 0;
    cin >> r;

    ld x = 0, y = r, d = 1.25 - r;

    //declare all variables before it
    initgraph(&gd,&gm, NULL);
    //draw here

    do
    {
        putpixel(100 + x, 100 + y, 15);
        putpixel(100 - x, 100 - y, 15);
        putpixel(100 - x, 100 + y, 15);
        putpixel(100 + x, 100 - y, 15);

        putpixel(100 + y, 100 + x, 15);
        putpixel(100 - y, 100 - x, 15);
        putpixel(100 - y, 100 + x, 15);
        putpixel(100 + y, 100 - x, 15);
        if(d < 0)
        {
            x = x + 1;
            y = y;
            d = d + 2 * x + 1;
        }
        else
```

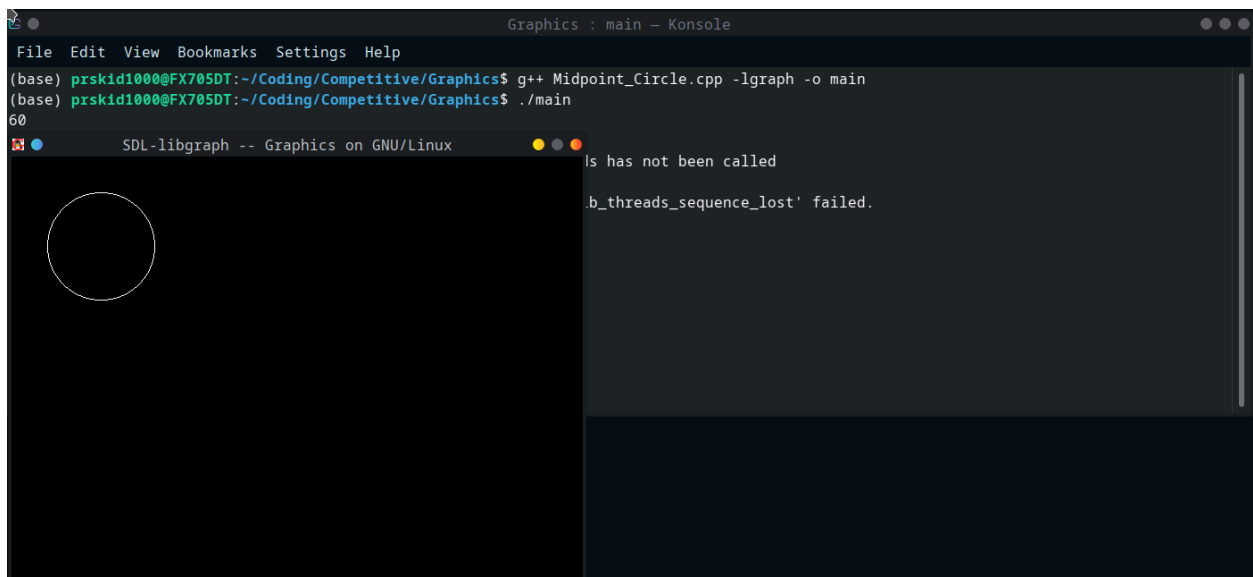

```

{
    x = x + 1;
    y = y - 1;
    d = d + 2 * x - 2 * y + 1;
}
delay(300);
}while(x < y);

//draw ends
getche();
closegraph();
return 0;
}

```

## Output

# ***EXPERIMENT NO.4***

## **Aim**

Draw a circle using Bresenham's algorithm

## **Theory**

We know the equation of the circle is  $f_c(x, y) = x^2 + y^2 = r^2$

We assume,

The distance between point  $P_3$  and circle boundary =  $d_1$

The distance between point  $P_2$  and circle boundary =  $d_2$

Now, if we select point  $P_3$  then circle equation will be

$$d_1 = (x_k + 1)^2 + (y_k)^2 - r^2$$

If we select point  $P_2$  then circle equation will be-

$$d_2 = (x_k + 1)^2 + (y_k - 1)^2 - r^2$$

Now, we will calculate the decision parameter  $(d_k) = d_1 + d_2$

$$d_k = 2(x_k + 1)^2 + (y_k)^2 + (y_k - 1)^2 - 2r^2$$

If  $d_k < 0$  then  $(x_{k+1}, y_k) = (x_k + 1, y_k)$

If  $d_k \geq 0$  then  $(x_{k+1}, y_k) = (x_k + 1, y_k - 1)$

Now, we will find the next decision parameter  $(d_{k+1})$

$$d_{k+1} = 2(x_{k+1} + 1)^2 + (y_{k+1})^2 + (y_{k+1} - 1)^2 - 2r^2$$

If  $d_k < 0$  then  $y_{k+1} = y_k$  (We select point  $P_3$ )

If  $d_k \geq 0$  then  $y_{k+1} = y_k - 1$  (We select point  $P_3$ )

Now, we calculate initial decision parameter  $(d_0)$

$$d_0 = d_1 + d_2$$

$$d_0 = 3 - 2r$$

## Program

```
#include<bits/stdc++.h>
#include<graphics.h>
#define ll long long int
#define ld long double
using namespace std;

int main()
{
    int gd = DETECT, gm, tmp = 0;

    ld r = 0;
    cin >> r;

    ld x = 0, y = r, d = 3 - 2 * r;

    //declare all variables before it
    initgraph(&gd,&gm, NULL);
    //draw here

    do
    {
        putpixel(100 + x, 100 + y, 15);
        putpixel(100 - x, 100 - y, 15);
        putpixel(100 - x, 100 + y, 15);
        putpixel(100 + x, 100 - y, 15);

        putpixel(100 + y, 100 + x, 15);
        putpixel(100 - y, 100 - x, 15);
        putpixel(100 - y, 100 + x, 15);
        putpixel(100 + y, 100 - x, 15);
        if(d < 0)
        {
            x = x + 1;
            y = y;
            d = d + 4 * x + 6;
        }
        else
```

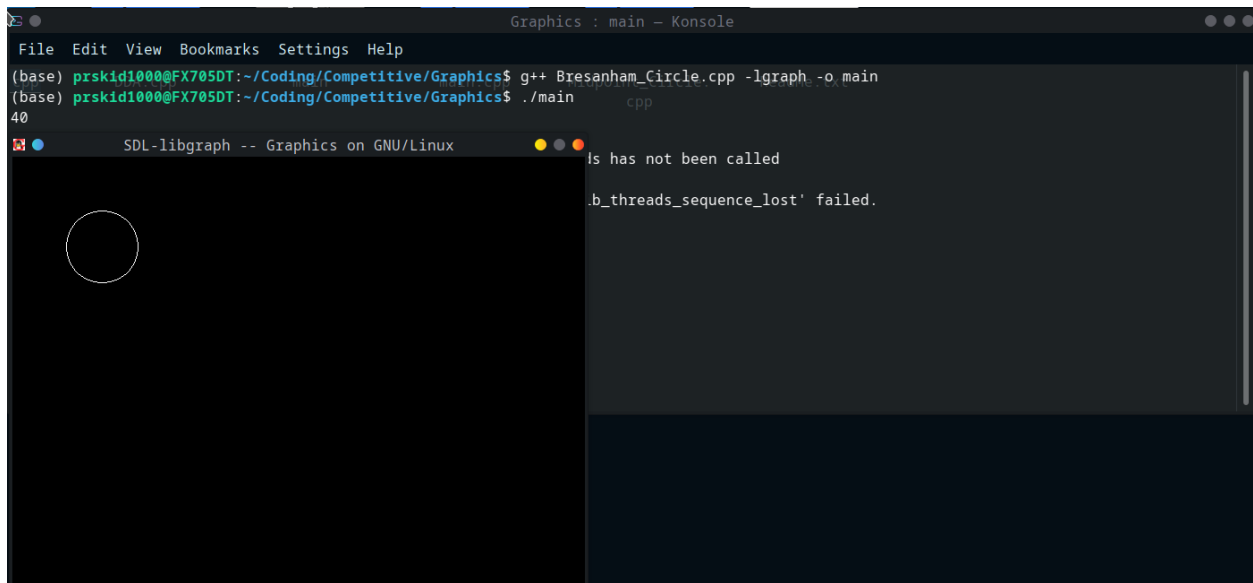

```

{
    x = x + 1;
    y = y - 1;
    d = d + 4 * x - 4 * y - 10;
}
delay(300);
}while(x < y);

//draw ends
getche();
closegraph();
return 0;
}

```

## Output

# EXPERIMENT NO.5

## Aim

Draw a eclipse using midpoint algorithm.

## Theory

Take input radius along x axis and y axis and obtain centre of ellipse. Initially, we assume ellipse to be centred at origin and the first point as :  $(x_0, y_0) = (0, r_y)$ .

Obtain the initial decision parameter for region 1 as:  $p1_0 = r_y^2 + 1/4 r_x^2 - r_x^2 r_y$   
For every  $x_k$  position in region 1 :

- If  $p1_k < 0$  then the next point along the is  $(x_{k+1}, y_k)$  and  $p1_{k+1} = p1_k + 2r_y^2 x_{k+1} + r_y^2$
- Else, the next point is  $(x_{k+1}, y_{k-1})$   
And  $p1_{k+1} = p1_k + 2r_y^2 x_{k+1} - 2r_x^2 y_{k+1} + r_y^2$

Obtain the initial value in region 2 using the last point  $(x_0, y_0)$  of region 1 as:  
 $p2_0 = r_y^2 (x_0 + 1/2)^2 + r_x^2 (y_0 - 1)^2 - r_x^2 r_y^2$

At each  $y_k$  in region 2 starting at  $k = 0$  perform the following task.

- If  $p2_k > 0$  the next point is  $(x_k, y_{k-1})$  and  $p2_{k+1} = p2_k - 2r_x^2 y_{k+1} + r_x^2$
- Else, the next point is  $(x_{k+1}, y_{k-1})$  and  $p2_{k+1} = p2_k + 2r_y^2 x_{k+1} - 2r_x^2 y_{k+1} + r_x^2$

Now obtain the symmetric points in the three quadrants and plot the coordinate value as:  $x = x + x_c$ ,  $y = y + y_c$

Repeat the steps for region 1 until  $2r_y^2 x > 2r_x^2 y$

## **Aim**

Draw text using library functions

## **Theory**

- **setcolor():** It will set the cursor colour and hence anything written on the output screen will be of the colour as per setcolor().
- **settextstyle():** It set the text font style, its orientation(horizontal/vertical) and size of font.
- **outtextxy() :** It will print message passed to it at some certain coordinate (x,y).

## **Program**

**Note: Program was run in turboc++ inside dosbox**

```
#include<stdio.h>
#include<graphics.h>
#include<dos.h>

void printMsg()
{
    int gdriver = DETECT,gmode,i;
    initgraph(&gdriver,&gmode,"C:\\TC\\BGI");

    for (i=3; i<7; i++)
    {
        setcolor(i);
        settextstyle(i,0,i);
        outtextxy(100,20*i,"Geeks");
    }
}
```

```
        delay(500);
    }
    delay(2000);
}

int main()
{
    printMsg();
    return 0;
}
```

## Output

# ***EXPERIMENT NO.6b***

## **Aim**

Implementing boundary fill algorithm

## **Theory**

Boundary Fill Algorithm starts at a pixel inside the polygon to be filled and paints the interior proceeding outwards towards the boundary. This algorithm works only if the color with which the region has to be filled and the color of the boundary of the region are different. If the boundary is of one single color, this approach proceeds outwards pixel by pixel until it hits the boundary of the region.

Boundary Fill Algorithm is recursive in nature. It takes an interior point( $x, y$ ), a fill color, and a boundary color as the input. The algorithm starts by checking the color of ( $x, y$ ). If it's color is not equal to the fill color and the boundary color, then it is painted with the fill color and the function is called for all the neighbours of ( $x, y$ ). If a point is found to be of fill color or of boundary color, the function does not call its neighbours and returns. This process continues until all points up to the boundary color for the region have been tested.

The boundary fill algorithm can be implemented by 4-connected pixels or 8-connected pixels.

## Program

```
#include<bits/stdc++.h>

#include<graphics.h>

#define ll long long int

#define ld long double

return 0;
```

# Output

The screenshot shows a code editor with a project named "Graphics" on the left. The main file, "main.cpp", is open, displaying a C++ program that uses SDL for graphics. The program initializes a window and a renderer, then enters a loop where it draws a blue rectangle. The output window, titled "SDL-ibgraph - Graphics on GNU/Linux", shows the program's execution, including several "request out of range" errors and a segmentation fault. The errors are related to the SDL\_Renderer::setTextureScaleMode method, which is called with an invalid texture ID. The program eventually crashes with a segmentation fault, as indicated by the "Segmentation fault (core dumped)" message.

## **Aim**

Implementing flood fill algorithm

## **Theory**

- Take the position of the starting point.
- Decide whether you want to go in 4 directions (N, S, W, E) or 8 directions (N, S, W, E, NW, NE, SW, SE).
- Choose a replacement color and a target color.
- Travel in those directions.
- If the tile you land on is a target, replace it with the chosen color.
- Repeat 4 and 5 until you've been everywhere within the boundaries

## **Program**

```
#include<bits/stdc++.h>
```

```
#include<graphics.h>
```

```
#define ll long long int
```

```
#define ld long double
```

```
//For outer loop
```

```
#define fr(i, start, stop, increment) for(i = start; i < stop; i += increment)
```

```
#define dfr(i, start, stop ,decrement) for( i = start; i >= stop; i -= decrement)
```

```

using namespace std;

```

## Output

# ***EXPERIMENT NO.6d***

## **Aim**

Implementing scan line algorithm

## **Theory**

It is an image space algorithm. It processes one line at a time rather than one pixel at a time. It uses the concept area of coherence. This algorithm records edge list, active edge list. So accurate bookkeeping is necessary. The edge list or edge table contains the coordinate of two endpoints. Active Edge List (AEL) contain edges a given scan line intersects during its sweep. The active edge list (AEL) should be sorted in increasing order of x. The AEL is dynamic, growing and shrinking.

- Start algorithm
- Initialize the desired data structure
- Create a polygon table having color, edge pointers, coefficients.  
Establish edge table contains information regarding, the endpoint of edges, pointer to polygon, inverse slope. Create Active edge list. This will be sorted in increasing order of x. Create a flag F. It will have two values either on or off.
- Perform the following steps for all scan lines
  - i) Enter values in Active edge list (AEL) in sorted order using y as value
  - ii) Scan until the flag, i.e. F is on using a background color.
  - iii) When one polygon flag is on, and this is for surface S1 enter color intensity as I1 into refresh buffer

- iv) When two or image surface flag are on, sort the surfaces according to depth and use intensity value  $S_n$  for the  $n$ th surface. This surface will have least  $z$  depth value
- v) Use the concept of coherence for remaining planes.
- Stop Algorithm

# ***EXPERIMENT NO.7***

## **Aim**

Write a program for performing the basic 2D transformations such as translation, scaling, rotation, shearing and reflection for 2D object.

## **Theory**

### **Algorithm for scaling**

- For each point P (x, y) do the following

$$\begin{matrix} x' & Sx & 0 & 0 & x \\ y' & 0 & Sy & 0 & y \\ 1 & 0 & 0 & 1 & 1 \end{matrix}$$

- Then finally plot the lines joining those points

### **Algorithm for Rotation**

- For each point P (x, y) do the following

$$\begin{matrix} x' & \cos(a) & -\sin(a) & 0 & x \\ y' & \sin(a) & \cos(a) & 0 & y \\ 1 & 0 & 0 & 1 & 1 \end{matrix}$$

- Then finally plot the lines joining those points

### **Algorithm for Shearing**

- For each point P (x, y) do the following

$$\begin{matrix} x' & 1 & Sx & 0 & x \\ y' & Sy & 1 & 0 & y \\ 1 & 0 & 0 & 1 & 1 \end{matrix}$$

- Then finally plot the lines joining those points

## Algorithm for Reflection

- For each point P (x, y) do the following

$$\begin{matrix} x' & rx & 0 & 0 & x \\ y' & 0 & ry & 0 & x & y \\ 1 & 0 & 0 & 1 & 1 \end{matrix}$$

- Then finally plot the lines joining those points

## Algorithm for Translation

- For each point P (x, y) do the following

$$\begin{matrix} x' & 1 & 0 & Tx & x \\ y' & 0 & 1 & Ty & x & y \\ 1 & 0 & 0 & 1 & 1 \end{matrix}$$

- Then finally plot the lines joining those points

## Program

Write a program

```
#include<bits/stdc++.h>
```

```
#include<graphics.h>
```

```
#define ll long long int
```

```
#define ld long double
```

```
using namespace std;

## **Aim**

Write a program to create two-dimensional object car as shown in figure.

## **Theory**

- Use **line()**, **arc()** and **circle()** function to draw the car

## **Program**

```
#include<bits/stdc++.h>

#include<graphics.h>

#define ll long long int
#define ld long double

using namespace std;

int main()
{
    int gd = DETECT, gm, tmp = 0;

    //declare all variables before it

    initgraph(&gd,&gm, NULL);

    //draw here

    line(200,50, 300, 50);
```

```
line(200, 50, 150, 80);  
line(300, 50, 400, 80);  
line(100, 80, 450, 80);  
line(100, 80, 100, 110);  
line(450, 80, 450, 110);  
circle(170, 110, 20);  
circle(390, 110, 20);  
line(100, 110, 150, 110);  
line(190, 110, 370, 110);  
line(410, 107, 450, 110);  
//draw ends  
getche();  
closegraph();  
return 0;  
}
```

## Output

# ***EXPERIMENT NO.9***

## **Aim**

Implementation of Line Clipping using Cohen - Sutherland Algorithm.

## **Theory**

Nine regions are created, eight "outside" regions and one "inside" region.

For a given line extreme point (x, y), we can quickly find its region's four-bit code. Four-bit code can be computed by comparing x and y with four values (x\_min, x\_max, y\_min and y\_max).

- If x is less than x\_min then bit number 1 is set.
- If x is greater than x\_max then bit number 2 is set.
- If y is less than y\_min then bit number 3 is set.
- If y is greater than y\_max then bit number 4 is set

There are three possible cases for any given line.

- Completely inside the given rectangle: Bitwise OR of region of two end points of line is 0 (Both points are inside the rectangle)

- Completely outside the given rectangle: Both endpoints share at least one outside region which implies that the line does not cross the visible region. (bitwise AND of endpoints! = 0).
- Partially inside the window: Both endpoints are in different regions. In this case, the algorithm finds one of the two points that is outside the rectangular region. The intersection of the line from outside point and rectangular window becomes new corner point and the algorithm repeats

- Assign a region code for two endpoints of given line.
- If both endpoints have a region code 0000 then given line is completely inside.
- Else, perform the logical AND operation for both region codes.
  1. If the result is not 0000, then given line is completely outside.
  2. Else line is partially inside.
  3. Choose an endpoint of the line that is outside the given rectangle.
    - a. Find the intersection point of the

- rectangular boundary (based on region code)
  - b. Replace endpoint with the intersection  
and update the region code.
  - c. Repeat step 2 until we find a clipped line either  
trivially accepted or trivially rejected.
4. Repeat step 1 for other lines

## Program

```
#include <bits/stdc++.h>

#include <graphics.h>

using namespace std;

int xmin, xmax, ymin, ymax;

    }  
    delay(4000);  
    getch();  
    // For Closing the graph.  
    closegraph();  
    return 0;  
}
```

# Output

The screenshot shows an IDE with a project named 'Graphics'. The file explorer on the left lists several C++ files, including 'main.cpp'. The main.cpp file is open in the editor, showing the following code:

```
160  xmin = 40;
161  xmax = 100;
162  ymin = 40;
163  ymax = 80;
164
165  /*for(int i = 0; i < 4; i++)
166  {
167      int x1, y1, x2, y2;
168      cin >> x1 >> y1 >> x2 >> y2;
169
170      mylines[i].x1 =
171      mylines[i].y1 =
172      mylines[i].x2 =
173      mylines[i].y2 =
174  }*/
175
176  initgraph(&gd, &gm,
177
```

Below the code editor, there is a terminal window showing the execution output. The output is as follows:

```
-o main
alled
ce_lost' failed.
```

The terminal window also shows some error messages from the system:

# ***EXPERIMENT NO.10***

## **Aim**

Implementation of Polygon Clipping using Sutherland- Hodgeman Algorithm.

## **Theory**

- For each edge  $e$  clip the given polygon against  $e$
- The edge (of clipping area) is extended infinitely to create a boundary and all the vertices are clipped using this boundary. The new list of vertices generated is passed to the next edge of the clip polygon in clockwise fashion until all the edges have been used. There are four possible cases for any given edge of given polygon against current clipping edge  $e$ .
  - ❖ **Both vertices are inside:** Only the second vertex is added to the output list
  - ❖ **First vertex is outside while second one is inside:** Both the point of intersection of the edge with the clip boundary and the second vertex are added to the output list
  - ❖ **First vertex is inside while second one is outside:** Only the point of intersection of the edge with the clip boundary is added to the output list
  - ❖ **Both vertices are outside:** No vertices are added to the output list
- If the vertices of the clipper polygon are given in clockwise order then all the points lying on the right side of the clipper edges are inside that

polygon. This can be calculated using

Given that the line starts from  $(x_1, y_1)$  and ends at  $(x_2, y_2)$

$$P = (x_2 - x_1)(y - y_1) - (y_2 - y_1)(x - x_1)$$

if  $P < 0$ , the point is on the right side of the line

$P = 0$ , the point is on the line

$P > 0$ , the point is on the left side of the line

- If two points of each line(1,2 & 3,4) are known, then their point of intersection can be calculated using the formula :-

$$(P_x, P_y) = \left( \frac{(x_1 y_2 - y_1 x_2)(x_3 - x_4) - (x_1 - x_2)(x_3 y_4 - y_3 x_4)}{(x_1 - x_2)(y_3 - y_4) - (y_1 - y_2)(x_3 - x_4)}, \frac{(x_1 y_2 - y_1 x_2)(y_3 - y_4) - (y_1 - y_2)(x_3 y_4 - y_3 x_4)}{(x_1 - x_2)(y_3 - y_4) - (y_1 - y_2)(x_3 - x_4)} \right)$$

# EXPERIMENT NO.11

## Aim

Write a C-program for performing the basic transformations such as Translation, Scaling, Rotation for a given 3D object.

## Theory

### Algorithm for scaling

- For each point P (x, y, z) do the following
- $x' = x * tx$
- $y' = y * ty$
- $z' = z * tz$
- Then finally plot the lines joining those points

### Algorithm for Rotation

- For each point P (x, y, z) multiply the Point matrix with Rotation matrix

$$\begin{array}{c} \text{X-Rotation in 3D} \\ \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\phi & -\sin\phi & 0 \\ 0 & \sin\phi & \cos\phi & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \end{array} \quad \begin{array}{c} \text{Y-Rotation in 3D} \\ \begin{bmatrix} \cos\phi & 0 & \sin\phi & 0 \\ 0 & 1 & 0 & 0 \\ -\sin\phi & 0 & \cos\phi & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \end{array} \quad \begin{array}{c} \text{Z-Rotation in 3D} \\ \begin{bmatrix} \cos\phi & -\sin\phi & 0 & 0 \\ \sin\phi & \cos\phi & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \end{array}$$

- Then finally plot the lines joining those points

## Algorithm for Translation

- For each point P (x, y, z) do the following
  - $x' = x + tx$
  - $y' = y + ty$
  - $z' = z + tz$
- Then finally plot the lines joining those points

## Program

```
#include<bits/stdc++.h>

## Scaling

```
53 midy=maxy/2;
54
55 axis();
56
57 bar3d(midx+50,midy-100,midx+60,midy-90,5,1);
58
59 cout << "Enter scaling factors\\n\";
60 cin >> x >> y >> z;
61
62 cout << "After scaling\\n\";
63 bar3d(midx+(x*50),midy-(y*100
64 delay(3000);
65
66 cin >> x;
67 closegraph();
68 }
69
70
```

## Rotation

The screenshot shows an IDE with a C++ file named `3d_Transformation.cpp`. The code implements a 3D rotation around the z-axis. It defines a point `bar3d` at `(midx+50, midy-50, midz+60)` and calculates its new position after a 3.14/180 degree rotation. The code uses `SDL_Init` and `SDL_CreateWindow` to create a window titled "SDL-ilibgraph - Graphics on GNU/Linux". The window displays a 3D coordinate system with axes and a point. The code also includes a `main` function that prints the rotation angle and the new coordinates of the point.

```
89     cin >> o;  
90  
91     x1=50*cos(o*3.14/180)-100*sin(o*3.14/180);  
92     y1=50*sin(o*3.14/180)+100*cos(o*3.14/180);  
93     x2=60*cos(o*3.14/180)-90*sin(o*3.14/180);  
94     y2=60*sin(o*3.14/180)+90*cos(o*3.14/180);  
95  
96     cout << "After rotation about z axis\n";  
97     bar3d(midx+x1,midy-y1,midx+x2,midy-y2,midz+60);  
98     cin >> o;  
99  
100  
101     cout << "After rotation about x axis\n";  
102     bar3d(midx+50,midy-50,midx+60,midy-60,midz+60);  
103     cin >> o;  
104  
105  
106     cout << "After rotation about y axis\n";  
107     bar3d(midx+50,midy-50,midx+60,midy-60,midz+60);  
108     cin >> o;  
109  
110     return 0;  
111 }
```

The terminal output shows the following:

```
main: ./../src/main: poll_for_event: Assertion '!xcb_xlib_threads_sequence_lost' failed.  
After rotating angle  
0  
After rotation about z axis  
0  
After rotation about x axis  
0  
After rotation about y axis  
0
```
